2.1 Robotic Maintenance of Industrial Installations

2.1.1 Introduction

This project is a small step towards a larger long-term goal concerning robotic maintenance. This section puts the following background theory, and the implementation described in chapter 3, into the context of automated robotic maintenance on industrial installations. It is important to describe how maintenance and inspection of industrial installations is done today, before application of robotic maintenance is discussed.

2.1.2 Potential Maintenance Tasks

Hidden failure modes: PFD: What is the probability that a device (Fire detector, shut down valve, etc.) will fail when needed? Solution: Periodic maintenance.

2.1.3 Offshore Installations

Corrosion

Offshore installations are regularly, if not continuously, exposed to harsh weather conditions in the form of wind and seawater. Presence of seawater, either through direct contact or in the form of drops and vapor, forms a very corrosive environment. The offshore and marine environment is classified as the most corrosive environment in ISO 12944[ER12]. It is essential to provide countermeasures to ensure safe and reliable operation over the lifetime of the installation. Common corrosion prevention methods are [ER12]:

- Sacrificial Anodes.
- Cathodic Protection (CP) in the form of a DC-current.

4 2. BACKGROUND THEORY

- Protective coating.

In terms of maintenance, the sacrificial anodes can be subjected to periodic inspections and replacements, which could be done a robot. CP can more easily be implemented with automated self tests, and should normally not require any inspections and maintenance [ER12]. Application of protective coating should ideally be applied in the controlled environment of a workshop. If protective coating is to be applied at sea, one should strive to make the conditions as favorable as possible.

Fatigue

Waves, wind, water currents and other forces subject offshore installations to structural stress.

2.2 Robotic Maintenance Today

Gas leak detection: [SWB⁺14]. DARPA robotic challenge. Industrial ROS.

Trends and Potential

The typical pre-programmed assembly robots still dominate the robotic market. They are usually found in manufacturing plants and large scale production[ifr], e.g. the automotive industry, where they perform dull, tedious tasks much faster and with higher accuracy than people. A notable trend in modern robotics is increased human-robot collaboration[Bog16]. Many new robots are being build for the human workspace, both in terms of safety and collaborative functionality. This trend is a step along the way of moving robots out of the controlled environment of a factory floor, and into the real world where a high degree of autonomy is required.

A report by Metra Martech[GC11], a market research firm referenced to by International Federation of Robotics (IFR)¹, points to three areas with a high potential for robotic applications:

- Dangerous jobs, e.g. handling dangerous materials or work in high risk environments.
- Jobs that are economically infeasible in a high wage economy.
- Work which is impossible or highly inconvenient for humans, e.g. space exploration, subsea maintenance or assembly of heavy components.

¹http://www.ifr.org/robots-create-jobs/

All of these factors motivate the development of robots for autonomous robotic maintenance.

Subsea Maintenance and Inspection

Subsea maintenance is perhaps the field that have seen the greatest advancements in autonomous inspection and maintenance. As offshore installations are moved to the seabed, maintenance and inspection has become a significant challenge. This has resulted in a widespread use of Remotly Operated Vehicles (ROV's). Recent developments in other fields, e.g. computer vision, human-robot collaboration and machine learning, has resulted in new Autonomous Inspection Vehicles (AIV's) and Autonomous Underwater Vehicles (AUV's) capable of performing inspection and simple maintenance tasks

Figure 2.1: Subsea 7's AIV. This is the first commercial autonomous inspection vehicle for subsea operations [pre]

autonomously[JWA⁺12][RCR⁺15]. A driving factor behind the transition from ROV's to AUV's is cost reduction through increased offshore campaign efficiency.

Disaster Responce

Robots in disaster response, relief and recovery solve many of the same problems faced by maintenance robots. Disasters, such as the Tsunami which struck Japan in 2011, has proved to be particularly demanding for robots, both in terms og technical difficulties as well as the process of deployment. Many of the robots which were deployed at Fukushima were already aging, and the operators had to receive training before deployment, thus increasing the response time[KFO12]. A paper from Japan Atomic Energy Agency [KFO12] highlights how the lack of stakeholder involvement could have been the cause

Figure 2.2: Team HRP2-Tokyo's robot turning a valve during DARPA Robotics Challenge 2015 (Image credits: DARPA Robotics Challenge)

6 2. BACKGROUND THEORY

of long response times. The same paper points out that the robots were developed for the sake of development, and not with emergency response as the main purpose [KFO12].

DARPA Robotics Challenge (DRC)[DRC] was launched in response to the Fukushima disaster of 2011. The purpose of the competition is to accelerate innovation, research and development in robotics for disaster response in cases where humans cannot operate. Some of the tasks the competitors faces in 2015 include valve turning, traversing rubble and driving a vehicle through a course before egressing out of the vehicle.

Robotic Maintencance of Process Plants

Fraunhofer Institute for Manufacturing Engineering and Automation² has developed a robot, Mobile Inspection and Monitoring Robot, experimental (MIMROex), with capabilities which are quite similar to the prototype used during the work on this thesis. MIMROex is equipped with a camera for visual inspections as well as microphones, vibration and sensors for fire and gas detection. It is also certifiable in accordance with the explosion protection standard IEC 60079[MIM].

2.3 Modelling and Simulation

2.3.1 Some Terminology

Coordinate Systems and Poses

Robot Joints

All links are connected to each other by joints.

Coordinate systems are essential in the field of robotics.

2.3.2 Robot Modelling

2.3.3 Simulating in Gazebo

2.4 ROS

2.4.1 Introduction

The Robot Operating System (ROS) is a collection of software libraries, tools and drivers intended for robot software development. A ROS installation can be tailored

²http://www.ipa.fraunhofer.de/en.html

to meet the demands of a wide range of robots with varying complexity. ROS is usually installed in the form of an already built Debian-package. These packages are only compatible with a few versions of Ubuntu which are specified on the ROS homepage. When installed and configured, ROS will run on top of Linux, and can be perceived as and extention of Linux itself. Installing ROS from source is possible, but not recommended [ROSb].

Roots of ROS can be traced back to Stanford University at the beginning of the 2000s. At Stanford, several robotics software frameworks, including Stanford AI Robot (STAIR) and the Personal Robot (PR) program, were created to provide dynamic, flexible and well tested foundations for further robot development and research. In 2007, a nearby start-up company and robot incubator, Willow Garage, sought to build upon these concepts, and initiated a collaborative and open development process of a new software framework. This framework eventually became ROS[ROSa][QGS15]. The framework can be used under the BSD open-source license, which means that ...[?] Today, ROS comes in many forms and comprise hundreds of advanced packages, algorithms and drivers, making it applicable for hobbyists, industrial automation, research and everything in between.

2.4.2 Important ROS Concepts

The following descriptions are included in order to provide a complete, self-contained description of the project implementation. Similar descriptions can be found on the official ROS website³, as well as in any book on ROS (for example [QGS15]).

The ROS Graph

A ROS system comprise a set of small programs that communicate with each other through messages. These programs become nodes in the ROS graph. The nodes communicate with each other by publishing and subscribing to topics that form the edges of the graph. A topic must have the format of one of the specific data types provided by ROS. For example, a node which receives temperature data from a thermometer, may publish the data as a topic on the ROS system with the type sensor_msgs/Temperature. There are many other data formats, e.g. velocity messages, geometry_msgs/Twist; images, sensor_msgs/Image; odometry messages, nav_msgs/Odometry and so on. Each node in the graph are typically POSIX processes, and the edges are TCP connections[QGS15].

roscore

roscore is an essensial part of any ROS system as it enables nodes to communicate with each other. When a node is started, it will inform roscore of which topics it

³http://www.ros.org/

8 2. BACKGROUND THEORY

publishes and which topics it wish to subscribe to. Then, roscore will provide the information which allows the node to form a peer-to-peer connection to other nodes.

2.4.5 Notable Robots Running ROS

PR2 - Personal Robot 2 PR2 is one of the first robots designed to run ROS [QGS15], and also one of the most advanced and capable robots with ROS today.

TurtleBot TurtleBot is a cheaper ROS-ready alternative to PR2.

Robonaut 2 Robonaut 2, a dexterous humanoid robot, currently resides within the International Space Station (ISS) 400 km above the earth's surface. In 2014, a SpaceX Dracon capsule brought ROS as well as a pair of legs for Robonaut up to the ISS[ROSc]. Robonaut is designed for research on human-robot collaboration in space, and human-like tasks. For more information, follow **this link**⁴ to a talk on ROS in space from ROSCon 2014.

Being the first robot with ROS to be launched into space,

Example of an industrial robot with ROS goes here! TODO!!!!!!!!!

Different Methods for Depth Perception

In the context of this thesis, a depth camera is considered to be a sensor which the functionality of a regular video camera

A depth camera can be described as a regular color video camera with the ability to create spatial images. In the context of this thesis, a depth camera can more precisely be described as a RGB-D camera, which is short for red, green, blue and depth camera. A regular RGB camera will project a spatial scene onto a rectangular pixel grid, where each pixel contains intensity values for red, green and blue colors. These pixel values represents the detected scene. A major problem with RGB cameras is the significant loss of information. The information loss is mostly a consequence of 3d to 2d projection and digital quantization. RGB-D cameras have the means to reduce this information loss by mapping the pixel values to spatial coordinates, turning each pixel into voxels and the image into a point cloud of voxels.

Different variations of depth cameras will usually fall into one of two categories: active or passive. Passive sensors perceive the surroundings as it is, without actively interfering with the environment as a part of the sensing process. A typical passive RGB-D sensor is the stereo camera. Stereo cameras use a stream of synchronized image pairs to perceive depth. The image pairs are displaced along the horizontal axis, and the depth information is extracted by searching for mutual information in

the image pairs. How far the information is displaced from the left to the right image is directly related to how far away from the camera the information source is located.

Active sensors depend on some form of projection onto the surroundings. For depth cameras, the projection is usually in the form of laser or infra red light. In RGB-D cameras it is essential that the projected light is distinguishable from the visible spectrum. The Kinect sensor used in this project is an example of an active RGB-D sensor. A proper introduction to the Kinect, will follow shortly.

Natural User Interfaces - Origin of the Kinect

Forslag 1: When a group of designers are developing a new Graphical User Interface (GUI), they will often use a conceptual model when planning their design. The conceptual model is the mental model the designers want to put into the head of the user. All users will develop their own individual mental model, which is their high level understanding of how the GUI works. A conceptual model may contain metaphors for things the user already is familiar with. A painting program for example may use a metaphor for a canvas, paint brushes and palettes. When the mouse icon changes to a paint brush, most users will have an intuitive understanding of what it can do and how it is used. A Natural user interface (NUI) will seek to remove the metaphors and create a more seamless interaction between the user and the machine. Some NUIs may allow a user to write text with a pen instead of a keyboard, or dictate a letter with their voice while the computer converts audio into text.

Forslag 2: The idea behind a NUI is to make Human-Machine Interaction (HMI) as seamless and natural as possible. A NUI allows the user to communicate without tools such as a keyboard or a mouse. For decades, NUIs have only existed as ideas, science fiction or research projects. This has changed dramatically over the last ten years, and NUIs can now be considered to be ubiquitous. Today, the most common form of NUIs is the touch screen found in smart phones and tablets.

The Microsoft Kinect sensor was initially designed as a NUI for the Xbox 360 gaming console. The sensor allows users to use gestures and sounds to play console games. Later on, Microsoft has released SDKs, enabling developers to create NUI applications for for Windows.

The modern RGB-D sensors which are commonly used in robot research projects today were initially intended as NUI.

Kinect for Xbox 360

Kinect for Xbox 360 is the RGB-D sensor used in this project. The device was initially intended as a NUI for gaming and office applications. Possible use cases were inspired by early NUI research at Massachusetts Institute of Technology (MIT) and, later on, the science fiction movie Minority Report, where Tom Cruice interacts with a computer by using hand gestures [WA12]. The Kinect sensor is equipped with a depth sensor, a regular color camera, a microphone array and a tilt motor. The color camera in combination with the depth sensor forms what is usually referred to as a rgb-d sensor, i.e. a combined color and depth camera. This feature, combined with the relaticely low cost and accessability of the sensor as contributed to make the Kinect very popular in research projects related to Simultanious Localization And Mapping (SLAM) and robotics.

Today, the Kinect for Xbox 360 has been succeeded by the Kinect for Xbox One, and is now considered to be a legacy device. Those considering to use the legacy Kinect should be aware of that it is becoming increasingly difficult, if not already impossible, to get hold of a new Kinect for Xbox 360.

2.8.2 Plannar Laser Sensors (LIDAR)

A plannar laser sensor, known as e.g. laser proximity sensors or laser radars, can all be referred to as LIDARs.

Scanning Laser Range Finder, URG-04LX-UG01

- 2.8.3 Odometers
- 2.8.4 Sensor Fusion
- 2.9 Simultanious Localization and Mapping (SLAM)

2.9.1 Introduction to SLAM

SLAM, also known as Concurrent Localization and Mapping (CLM), is a class of solutions to the problem of determining an agents location and pose in an unknown environment, while simultaneously mapping the same environment.

2.9.2 RTAB-Map

Real-Time Appearance-Based Mapping (RTAB-Map) is a graph-based SLAM system intended to handle the "kidnapped robot-problem" as well as multi-session mapping [LM14]. Both these problems become relevant whenever a robot is shut down and moved to a new unknown location in the same area.

2.9.3 Octomap

Figure 2.3: Awesome Image

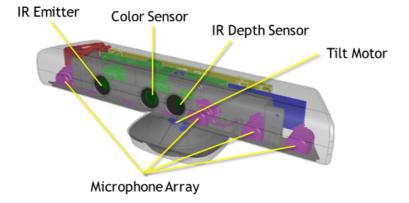

Figure 2.4: Awesome Image

Implementation procedure for mobile robot:

- Decide on ROS message interface.
- Write interfaces for the motor drivers.
- Create a description of the physical structure and properties of the robot in Unified Robot Description Format (URDF).
- Extend the model to enable simulation in Gazebo.
- Publish coordinate transform data via tf and visualize it in rviz.
- Add sensors, with driver and simulation support.
- Apply algorithms for navigation and other functionality.

3.1 Modelling

3.1.1 Physical Dimensions

The inertia tensor:

$$I = \begin{bmatrix} I_{xx} & I_{xy} & I_{xz} \\ I_{yx} & I_{yy} & I_{yz} \\ I_{zx} & I_{zy} & I_{zz} \end{bmatrix}$$
(3.1)

Inertia tensor for a solid, uniform cylinder where the radius r is measured in parallel to the x-y plane, and h is parallel to the z axis:

$$I_{cylinder} = \frac{1}{12}m \begin{bmatrix} (3r^2 + h^2) & 0 & 0\\ 0 & (3r^2 + h^2) & 0\\ 0 & 0 & r^2 \end{bmatrix}$$
(3.2)

Inertia tensor for a solid, uniform cuboid. The subscript of l indicates which axis l is measured along:

$$I_{cuboid} = \frac{1}{12} m \begin{bmatrix} (l_y^2 + l_z^2) & 0 & 0\\ 0 & (l_x^2 + l_z^2) & 0\\ 0 & 0 & (l_x^2 + l_y^2) \end{bmatrix}$$
(3.3)

3.1.2 Coordinate Frames

3.2 Simulations

3.3 ROS Nodes for Motion Control

3.3.1

3.4 Operator Control Station (OCS)

The Operator Control Station (OCS) allows an operator to control and monitor the robot through a graphical user interface. MainWindow

3.4.1 Graphical User Interface

A Qt-based GUI...

Chapter Testing

- 4.1 Testplan
- 4.2 Results
- 4.3 Discussion

Chapter Discussion

6.1 Future Work

6.1.1 Autonomous Non-Destructive Testing

Advancements in Artificial Intelligence (AI), big data and machine learning opens up exciting possibilities for autonomous Non-destructive Testing (NDT). Branches of this technology is usually encountered in the context of image recognition, i.e. teaching machines to understand what they see. The same concepts may be applied to forms of NDT besides regular visual sensor input, such as ultra sound or eddy currents for corrosion detection.

6.1.2 Large Scale Kinect Fusion - Kintinous

Kinect Fusion has great potential for augmented reality. Augmented reality is a concept which blends the real and virtual environment. This opens up opportunities to create realistic and immersive training scenarios for the operators. Unfortunately, Kinect Fusion is limited reconstructing a rather small volume depending on the resolution. By varying the resolution, volumes can at the least cover a normal office desk and at the most cover a small room [?]

Kintinous...

A guide on how to build Kintinous can be found at https://github.com/mp3guy/Kintinuous. The procedure is complicated, as it usually is for experimental builds. It is recommended to attempt the procedure on a fresh install of Ubuntu 14.04 or 15.04 [Kin].

- 6.2 Task Fulfillment
- 6.3 Task Fulfilment
- 6.4 Final Conclusion

Chapter

Setting Up the Project

7.1 Installation

7.1.1 Equipment List

Item List

Software list

Hector SLAM for ROS Install with

sudo apt-get install ros-indigo-hector-slam

Compatibility Issues

Indigo, Ubuntu etc.

7.1.2 Install Ubuntu

7.1.3 Download ROS

7.2 Configuring the Project

7.2.1 Configuring the ROS Workspace

7.2.2 Configuring the Bluetooth Connection

The Qt framework is used to simplify the implementation of the Bluetooth connection between the ROS graph and a remote device. Our ROS installation for this project already includes some variant of Qt version 4.8. While useful for creating new GUI applications, it lacks a Bluetooth API. The latest version of Qt, version 5.x, is equipped with libraries necessary for developing Bluetooth applications. This part of

the guide explain how to create a Qt 5 application which can be build by *catkin_make* and run as a *rosnode*.

1 - Install Qt5

Installing Qt5 for Linux is a straight forward procedure. Go to qt.io, and download the free version of Qt. All necessary instructions are provided. Qt5 may be installed in the home folder.

2- Enabling Qt5 in a ROS node

It is assumed that the ROS package "bluetooth_server", is located in a catkin workspace:

<NAME OF CATKIN WORKSPACE>/src/bluetooth_server

Inside this folder, open the file "CMakeLists.txt" and locate the following:

set(CMAKE_PREFIX_PATH "/home/vegard/Qt/5.5/gcc_64/lib/cmake/Qt5"
 "/home/vegard/Qt/5.5/gcc_64/lib/cmake/Qt5Core"
 "/home/vegard/Qt/5.5/gcc_64/lib/cmake/Qt5Bluetooth"

Change these paths to the correct paths on your system.

8.1 Introduction

This part of the thesis contains answers to some of the problems that was encountered over the course of the semester. The solutions are not complete or comprehensive, but may provide some quick fixes for any students that may continue working with this project.

8.2 Gazebo

8.2.1 Error [Node.cc.90] No namespace found

Solution: Remember to source the *gazebo* installation. In this case, with *gazebo-2.2* installed as recommended for ROS Indigo, the setup file can be sourced by entering

\$ source /usr/share/gazebo-2.2/setup.sh

8.2.2 Dependency Issues When Installing gazebo2

This problem was encountered after removing gazebo and then typing

\$ sudo apt-get upgrade

When typing

\$ sudo apt-get install -y gazebo2

the installation failed because some dependencies had been upgraded to an incompatible version. To solve this, take note of the missing dependencies listed after

entering the command above, open Ubuntu Software Center and select the History tab. Scroll down and locate the missing dependencies. They should have a red X next to them, indicating that they have been uninstalled. Then, enter the following command:

\$ sudo apt-get install <NAME OF THE UNINSTALLED DEPENDENCY>

gazebo2

8.3 Ubuntu

8.3.1 Ubuntu Freezes

Sometimes during work with the project, Ubuntu would freeze and become unresponsive to keyboard input and mouse clicks. The mouse could be moved around, but was otherwise unresponsive. This event occurred exclusively when using *RVIZ* and displaying a camera topic as an image in the lower left corner of the GUI. The following steps from a post at askubuntu.com, solves the problem [Reb]:

While holding Alt and SysReq (Print Screen), type REDSUB. Press each key properly, and allow a few seconds to pass between each keystroke so that each command has time to execute. This should cause the computer to reboot, and is supposedly safer than using the power button. Follow this link to the post for more details.
